

ABSTRACT

A display device for holding and displaying an article comprises a panel and one or more straps. The strap is movable between an article receiving position whereat the strap and panel form a laterally extending opening for laterally receiving the article therethrough, and an article engaging position whereat the article is frictionally engaged by the strap and panel in a direction perpendicular to the laterally extending opening to restrain lateral movement of the article from the opening. A pair of straps may be adjacent one another to provide vertical spacing between adjacent articles held in the respective straps. A pair of straps may be laterally spaced apart to display at least a portion of the article between the straps.
